20 ABSTRACT (Continue on reverse side if necessary and identity by block/number)

Consider a signal x(t) = f(t) + w(t),  $0 \nmid t \leq 1$ . Here the noise w(t) is an independent process, and f(t) is a function with only finitely many jumps, satisfies a Lipschitz' condition between any two consecutive jumps. This paper gives an algorithm to determine the number, locations and magnitudes of the jumps of f(t). The consistency and speeds of convergence are obtained. ## DETECTION OF THE NUMBER, LOCATIONS AND MAGNITUDES OF JUMPS

#### Y. Q. YIN

§1. <u>Introduction</u>. Jump detection or change-point detection is a very important problem in statistics and engineering. The problem can be stated in the following way:

Let x(t) = f(t) + w(t) be a stochastic process,  $0 \le t \le 1$ . Here w(t) is the noise process, Ew(t) = 0, and f(t) = Ex(t) is a function with only finitely many discontinuities  $t_1, \dots t_q$ . Suppose these discontinuities are all interior points of [0,1] and for each  $i=1,\dots,q$ ,  $f(t_i+0)$ ,  $f(t_i-0)$  exist and  $f(t_i+0) \ne f(t_i-0)$ . For definiteness, we suppose f is left continuous everywhere. Our problem is to estimate

- 1. the number q of discontinuities,
- 2. the positions  $t_1, \dots, t_q$  of these discontinuities;
- 3. the magnitudes  $f(t_i + 0) f(t_i 0)$  of the jumps,  $i = 1, \dots, q$ ; based on a sample  $x(\frac{k}{n}), k = 0, 1, \dots n$ .

In this paper, under mild conditions, we will give an algorithm to estimate q, i. e., define an estimator  $\hat{q}$  of q. For each  $i=1,\cdots q$ , we give an algorithm to estimate the position of the *ith* discontinuity point  $t_i$ , i. e., define an estimator  $\hat{t}_i$  of  $t_i$ ; we also define an estimator  $D_{n\hat{t}_i}$  for the jump at the *ith* discontinuity point.

We will prove that all these estimators are strongly consistent, or in other words, these estimators converge to the corresponding parameters as n, the number of sample points, tends to infinity, with probability one.

We also get the speed of convergence, for example for  $\hat{t}_i$  we get

$$|\hat{t}_i - t_i| = O\left(\frac{(\ln n)^{1+\alpha}}{n}\right)$$

for any  $\alpha > 0$ .

The complexity of computation of our algorithms is  $O(n \log n)$  approximately.

The basic hypotheses are two:

- 1. w(t) is a gaussian white noise.
- 2. There exists a positive constant K > 0, such that

$$|f(t)-f(s)| \leq K|t-s|$$
, if no  $t_i$  are in  $[s,t]$ .

The condition 1. can be relaxed to nongaussian white noises, but it would be difficult to relax 2.

In Section 2, we define the algorithms. In Section 3 we give the proofs.

Works on this topic mostly concentrate on the single jump problem, see the references listed at the rear of this paper. Especially no work has been done on the case when the number of jumps is unknown.

Acknowledgment. The author sincerely appreciates the encouragement and financial support of Dr. Krishnaiah, director of the Center for Multivariate Analysis, University of Pittsburgh.

§2. The Method for Detecting the Change Points. Let x(t) = f(t) + w(t) be a stochastic process,  $0 \le t \le 1$ . Here w(t) is a Gaussian white noise. f(t) = Ex(t) has only finitely many discontinuities  $t_1, \dots, t_q$ . All these discontinuities are in (0,1) and of the first kind, i. e.,  $f(t_i + 0)$ ,  $f(t_i - 0)$  exist for i = 1, ..., q.

Besides, suppose that there is a constant K > 0 such that  $|f(s) - f(t)| \le K|s - t|$ for any interval  $[s,t] \subset [0,1]$  not containing any discontinuities. Let

$$d_i = f(t_i + 0) - f(t_i - 0) \neq 0, \qquad i = 1, \dots, q,$$

and suppose

$$|d_1| \ge |d_2| \ge \cdots \ge |d_q|$$
, and if  $|d_i| = |d_j|$ , and  $i < j$ , then  $t_i < t_j$ .

Let  $m = m(n) \uparrow \infty$ ,  $m/n \to 0$ . Define

$$D_{nk} = \frac{x(\frac{k+1}{n}) + \cdots + x(\frac{k+m}{n})}{m} - \frac{x(\frac{k-1}{n}) + \cdots + x(\frac{k-m}{n})}{m},$$

for  $m \le k \le n - m$ .

Let  $h_n$  be a sequence of positive numbers,  $h_n \to 0$ ,  $\frac{m_n}{nh_n} \to 0$ , for definiteness, let  $h_n = (\ln_3 n / \ln_2 n)^{1/3}$ ,  $m_n = \ln n (\ln_2 n)^{2/3} (\ln_3 n)^{1/3}$  where  $\ln_1 n =$  $1 \wedge \ln n, |\ln n| = \ln_1(\ln_{k-1} n).$ 

$$I_1 = \arg\max_k \left\{ |D_{nk}| - \frac{k}{n}h_n \right\},$$
 $I_2 = \arg\max_k \left\{ |D_{nk}| - \frac{k}{n}h_n : |k - I_1| > 4m \right\},$ 
 $I_3 = \arg\max_k \left\{ |D_{nk}| - \frac{k}{n}h_n : |k - I_1| > 4m \text{ and } |k - I_2| > 4m \right\}, \cdots.$ 
If the definition is not unique, we choose the smallest one. At first, we state the

main theorem, which will be proved in Section 3.

Theorem 3.1. (1)  $\left| \frac{I_i}{n} - t_i \right| \leq \frac{2m}{n}$  for all large n, a. s,  $i = 1, \dots, q$ .

- (2)  $D_{nI_i} \to d_i$ , a. s.,  $i = 1, \dots, q$ .
- (3)  $D_{nI_i} = O(h_n)$ , a. s. for i > q.

We see from this theorem that the quantities defined above are strongly consistent estimators of the change points  $t_1, \cdots, t_q$  and the magnitudes  $d_i$  of changements. Furthermore we get the convergence rate

$$\left|\frac{I_i}{n} - t_i\right| \le \frac{2m}{n}$$
, for large  $n$ ,  $a$ .  $s$ .

from (1).

Theorem 3.1 does not supply a method to estimate the integer q, explicitly. But based on Theorem 3.1, we can construct a strongly consistent estimator of q in the following manner.

Let

(4) 
$$G_{nk} = \frac{1}{2^{k+1}} |D_{n,I_{k+1}}| + \frac{1}{2^{k+2}} |D_{n,I_{k+2}}| + \cdots + kc_n.$$

Here  $c_n > 0$  with the properties  $c_n \to 0$  and  $h_n/c_n \to 0$ . Let

$$\hat{q}_n = \arg\min_k G_{nk}.$$

Suppose we have proved Theorem 3.1. We are going to prove

Theorem 2.1.  $\hat{q}_n \rightarrow q$ , a. s.

<u>Proof.</u> If k < q, then, almost surely, as  $n \to \infty$ 

$$G_{nk} - G_{nq} \ge \frac{1}{2^{k+1}} |D_{nI_{k+1}}| + \dots + \frac{1}{2^q} |D_{nI_q}| - \frac{1}{2^k} h_n$$
  
  $+ (k-q)c_n \to \frac{1}{2^{k+1}} |d_{k+1}| + \dots + \frac{1}{2^q} |d_q| > 0,$ 

by (2) of Theorem 3.1. That means  $\hat{q}_n \neq k$  for large n.

If k > q, then, noticing  $|D_{nI_i}| \downarrow$ , as  $i \uparrow$ , by (3) of Theorem 3.1, we have for a constant C > 0,

$$G_{nk} - G_{nq} = -\frac{1}{2^{q+1}} \left| D_{nI_{q+1}} \right| - \dots - \frac{1}{2^k} \left| D_{nI_k} \right| - (k-q)c_n$$

$$\geq -\frac{1}{2^q} \left| D_{nI_{q+1}} \right| - (k-q)c_n$$

$$\geq -\frac{C}{2^q} h_n + (k-q)c_n = c_n \left( (k-q) - \frac{Ch_n}{2^{q+1}c_n} \right)$$

$$\geq c_n \frac{1}{2} (k-q) > 0$$

for n sufficiently large, almost surely. In this case  $\hat{q}_n \neq k$  either. So, almost surely, for n sufficiently large,  $\hat{q}_n = q$ .

#### §3. Proof of the Main Theorem. At first we prove an elementary lemma.

<u>Lemma</u>. Suppose f(t) is defined in the interval  $(t_0 - a, t_0 + a)$  for a positive number a. Suppose  $f(t_0 \pm 0)$  exist and are finite. Let  $I_n$  and  $m_n$  be two sequences of positive integers such that  $I_n/n \to t_0$ ,  $m_n/n \to 0$ ,  $m_n \to \infty$ . Let

$$A_n = -\frac{1}{m} \left( f\left(\frac{I-m}{n}\right) + \dots + f\left(\frac{I-1}{n}\right) - f\left(\frac{I+1}{n}\right) - \dots - f\left(\frac{I+m}{n}\right) \right),$$

where  $I = I_n$ ,  $m = m_n$ . Then, from  $\liminf_{n \to \infty} |A_n| \ge |f(t_0 + 0) - f(t_0 - 0)|$ , we can deduce that  $A_n \to f(t_0 + 0) - f(t_0 - 0)$ .

<u>Proof.</u> Without loss of generality, suppose  $\frac{I}{n} < t_0$  for all n. Let

$$k_n = \max \left\{ k : \frac{I+k}{n} < t_0, 0 \le k \le m \right\}.$$

Fix  $\epsilon > 0$ ,  $\exists \delta > 0$  such that  $t_0 - \delta < t < t_0 \implies |f(t) - f(t_0 - 0)| < \epsilon$ , and  $t_0 < t < t_0 + \delta \implies |f(t) - f(t_0 + 0)| < \epsilon$ .

Let N be such that as n > N,  $\left| \frac{I}{n} - t_0 \right| < \frac{\delta}{2}$ ,  $\frac{m}{n} < \frac{\delta}{2}$ . So, as n > N

$$A_n < -f(t_0 - 0) + \epsilon + (f(t_0 - 0) + \epsilon) \frac{k_n}{m} + \left(1 - \frac{k_n}{m}\right) (f(t_0 + 0) + \epsilon)$$

$$= \left(1 - \frac{k_n}{m}\right) (f(t_0 + 0) - f(t_0 - 0)) + 2\epsilon.$$

In the same way

$$A_n > \left(1 - \frac{k_n}{m}\right) \left(f(t_0 + 0) - f(t_0 - 0)\right) - 2\epsilon.$$

Thus,

$$|A_n| \leq \left|1 - \frac{k_m}{m}\right| |f(t_0 + 0) - f(t_0 - 0)| + 2\epsilon.$$

Therefore we must have  $\frac{k_n}{m} \to 0$ , thus  $A_n \to f(t_0 + 0) - f(t_0 - 0)$ .

Theorem 3.1. (1)  $|I_k/n - t_k| \leq \frac{2m}{n}$ , for all large n, a. s., for  $k = 1, \dots, q$ ;

- (2)  $D_{nI_k} \rightarrow d_k$ , a. s., for  $k = 1, \dots, q$ ;
- (3)  $D_{nI_k} = O(h_n)$ , a. s., for k > q.

<u>Proof.</u> 1. In this part, we prove  $\left|\frac{I_1}{n}-t_1\right| \leq \frac{2m}{n}$  for all large n, a. s. Introduce the following notations

$$\Delta_k = \frac{1}{m} \left\{ f\left(\frac{k+1}{n}\right) + \dots + f\left(\frac{k+m}{n}\right) \right\} - \frac{1}{m} \left\{ f\left(\frac{k-1}{n}\right) + \dots + f\left(\frac{k-m}{n}\right) \right\},$$

$$W_k^+ = \frac{1}{m} \left\{ w\left(\frac{k+1}{n}\right) + \dots + w\left(\frac{k+m}{n}\right) \right\},$$

$$W_k^- = \frac{1}{m} \left\{ w\left(\frac{k-1}{n}\right) + \dots + w\left(\frac{k-m}{n}\right) \right\}.$$

Let  $\hat{k}$  be such that  $|\hat{k}/n - t_1| = \min_{k} |k/n - t_1|$ ,  $\hat{k}$  depends only on n.

At first, we note that for  $|k/n - t_1| > 2m/n$ ,

(4) 
$$P\left(|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n \le |D_{nk}| - \frac{k}{n}h_n\right)$$
  
  $\le P\left(|\Delta_{\hat{k}}| - |\Delta_k| + \left(\frac{k-\hat{k}}{n}\right)h_n \le |W_k^+| + |W_k^-| + |W_{\hat{k}}^+| + |W_{\hat{k}}^-|\right).$ 

Because  $|\frac{k}{n} - t_1| > \frac{2m}{n}$ , the points  $\frac{k-m}{n}, \dots, \frac{k-1}{n}, \frac{k+1}{n}, \dots, \frac{k+m}{n}$  are all on the same side of  $t_1$ . If n is larger than some nonrandom number  $N_1 > 0$ , for any k with  $|t_1 - \frac{k}{n}| > \frac{2m}{n}$ , the interval  $\left[\frac{k-m}{n}, \frac{k+m}{n}\right]$  can contain at most one discontinuous point  $t_i$ . There are three possibilities:

- (a) No  $t_i$  in  $\left[\frac{k-m}{n}, \frac{k+m}{n}\right]$ ,
- (b)  $t_i \in \left[\frac{k-m}{n}, \frac{k+m}{n}\right], |d_i| = |d_1|$ , then  $t_i > t_1$ , and  $k > \hat{k}$ ,
- (c)  $t_i \in \left[\frac{k-m}{n}, \frac{k+m}{n}\right], |d_i| < |d_1|.$

For case (a) above,

$$|\Delta_{\hat{k}}| \ge |d_1| - 2K\frac{m}{n}, \quad |\Delta_k| \le K\frac{m+1}{n}$$

so,

$$|\Delta_{\hat{k}}| - |\Delta_k| + \frac{k - \hat{k}}{n} h_n \ge |d_1| - 3K \frac{m+1}{n} + \frac{k - \hat{k}}{n} h_n > \frac{1}{2} |d_1|,$$

for  $n \ge N_2 > 0$ ,  $N_2$  is a nonrandom constant.

For case (b),

$$|\Delta_{\hat{k}}| \geq |d_1| - 2K\frac{m}{n}, \quad |\Delta_k| \leq |d_1| + 2K\frac{m}{n},$$

so, for a constant c > 0,

$$|\Delta_{\hat{k}}| - |\Delta_k| + \frac{(k - \hat{k})}{n} h_n \ge -4K \frac{m}{n} + (t_i - t_1)h_n + o(h_n) \ge ch_n$$

when  $n \ge N_3 > 0$ ,  $N_3$  is nonrandom, c is a positive constant.

For case (c),

$$|\Delta_{\hat{k}}| - |\Delta_k| + \frac{(k - \hat{k})}{n} h_n \ge |d_1| - |d_i| + o(1)$$
  
  $\ge \frac{1}{2} (|d_1| - |d_i|) > 0$ 

when  $n \ge N_4 > 0$ ,  $N_4$  is nonrandom.

Thus, for  $n \ge max(N_1, N_2, N_3, N_4)$ , and for some constants  $c_1 > 0$ ,  $c_2 > 0$ ,

$$P\left(|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n \le |D_{nk}| - \frac{k}{n}h_n\right)$$

$$\le 4P\left(b_1h_n \le \left|\frac{v_1 + \dots + v_m}{m}\right|\right)$$

$$\le 4P\left(\frac{b_1}{\sigma}h_n\sqrt{m} \le |z|\right)$$

$$\le 8\frac{1}{\sqrt{2\pi}\frac{b_1}{\sigma}h_n\sqrt{m}}e^{-\frac{1}{2}\frac{b_1^2}{\sigma^2}h_n^2m}$$

$$\le b_2e^{-b_3\ln n\ln_3 n} = b_2n^{-b_3\ln_3 n}$$

if we choose  $h_n = \left(\frac{\ln_2 n}{\ln_2 n}\right)^{1/3}$ ,  $m = \ln n(\ln_2 n)^{2/3}(\ln_3 n)^{1/3}$ . Here  $b_1$ ,  $b_2$ ,  $b_3$  are positive constants,  $\ln_2 x = \ln \ln x$ ,  $\ln_3 x = \ln \ln x$ . Thus, the series

$$\begin{split} \sum_{n} P\bigg(|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_{n} &\leq |D_{n}k| - \frac{k}{n}h_{n}, \text{for some } k \text{ with} \left|\frac{k}{n} - t_{1}\right| > \frac{2m}{n}\bigg) \\ &\leq \sum_{n} nP\left(|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_{n} \leq |D_{nk}| - \frac{k}{n}h_{n}\right) < \infty. \end{split}$$

By Borel-Cantelli Lemma,

$$\begin{split} P\bigg(\exists N, s.t. n \geq N, \left|\frac{k}{n} - t_1\right| > \frac{2m}{n} \\ \Longrightarrow |D_{n\hat{k}}| - \frac{\hat{k}}{n} h_n > |D_{nk}| - \frac{k}{n} h_n\bigg) = 1 \end{split}$$

or,

$$P\left(\exists, N, s.t. n \ge N, |D_{n\hat{k}}| - \frac{\hat{k}}{n} h_n \le |D_{nk}| - \frac{k}{n} h_n \right)$$

$$\implies \left| \frac{k}{n} - t_1 \right| \le \frac{2m}{n} = 1.$$

Since  $|D_{nI_1}| - \frac{I_1}{n}h_n \ge |D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n$ ,

$$P\left(\exists N, s.t. n \geq N \Longrightarrow \left| \frac{I_1}{n} - t_1 \right| \leq \frac{2m}{n} \right) = 1.$$

This proves case k = 1 for (1).

Ву

$$|D_{nI_1}| - \frac{I_1}{n}h_n \ge |D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n$$

we have

$$\liminf |D_{nI_1}| \ge |d_1|.$$

So, by the elementary lemma, we get  $D_{nI_1} \rightarrow d_1$  a. s.

2. In this part we prove  $\left|\frac{I_i}{n} - t_i\right| \leq \frac{2m}{n}$  for all large n, a. s., and  $D_{nI_i} - d_i$  a. s., if  $2 \leq i \leq q$ . But we carry out the proof only for the case i = 2.

Let  $\hat{k}$  be such that  $|\frac{\hat{k}}{n} - t_2| = \min_{k} |\frac{k}{n} - t_2|$ , and suppose k is such that  $|\frac{k}{n} - t_1| > \frac{2m}{n}$  and  $|\frac{k}{n} - t_2| > \frac{2m}{n}$ . Suppose for these  $\hat{k}$  and k,  $|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n \le |D_{nk}| - \frac{k}{n}h_n$ , so that

$$|\Delta_{\hat{k}}| - |\Delta_{k}| + \frac{k - \hat{k}}{n} h_{n} \le |W_{k}^{+}| + |W_{k}^{-}| + |W_{\hat{k}}^{+}| + |W_{\hat{k}}^{-}|.$$

Since  $|\frac{k}{n}-t_1| > \frac{2m}{n}$ ,  $|\frac{k}{n}-t_2| > \frac{2m}{n}$ ,  $t_1$  and  $t_2$  are not in the interval  $[\frac{k-m}{n}, \frac{k+m}{n}]$ .  $\exists N_1 > 0$  nonrandom, such that as  $n \geq N_1$ ,  $[\frac{k-m}{n}, \frac{k+m}{n}]$  contains at most one discontinuity point. There are three possibilities:

- (a) No  $t_i$  in  $\left[\frac{k-m}{n}, \frac{k+m}{n}\right]$ ,
- (b)  $t_i \in [\frac{k-m}{n}, \frac{k+m}{n}], |d_i| = |d_2|, \text{ of course } i > 2, t_i > t_2.$
- (c)  $t_i \in [\frac{k-m}{n}, \frac{k+m}{n}], |d_i| < |d_2|.$

For (a), we have

$$|\Delta_{\hat{k}}| \ge |d_2| - K \frac{2m}{n}, \quad |\Delta_k| \le K \frac{2m}{n},$$

and then as  $n \geq N_2$ ,  $N_2$  nonrandom,

$$|\Delta_{\hat{k}}|-|\Delta_k|+\frac{k-\hat{k}}{n}h_n\geq |d_2|-\frac{4Km}{n}-h_n\geq \frac{1}{2}|d_2|.$$

For (b),

$$|\Delta_{\hat{k}}| \geq |d_2| - K \frac{2m}{n}, \quad |\Delta_k| \leq |d_2| + K \frac{2m}{n},$$

and as  $n \geq N_3$ ,  $N_3$  nonrandom, we have

$$|\Delta_{\hat{k}}| - |\Delta_k| + \frac{k - \hat{k}}{n} h_n \ge -K \frac{4m}{n} + \frac{k - \hat{k}}{n} h_n$$

$$\ge \left( -K \frac{4m}{nh_n} + t_i - t_2 + o(1) \right) h_n \ge bh_n,$$

for constant b > 0.

For case (c), just in the same way, we can show that as  $n \geq N_4$ ,  $N_4$  nonrandom,

$$|\Delta_{\hat{k}}| - |\Delta_k| + \frac{k - \hat{k}}{n} h_n \ge \frac{1}{2} (|d_2| - |d_i|) > 0.$$

therefore as  $n \geq max(N_1, N_2, N_3, N_4)$ ,

$$P\left(|D_{nk}| - \frac{\hat{k}}{n}h_n \le |D_{nk}| - \frac{k}{n}h_n\right)$$

$$\le 4P\left(b_1h_n \le \left|\frac{v_1 + \dots + v_m}{m}\right|\right)$$

$$\le 4P(b_2h_n\sqrt{m} \le |z|) \le b_2n^{-b_3\ln_2 n}$$

for positive constants  $b_1$   $b_2$ ,  $b_3$ . Here  $v_1, \dots, v_m$ , z have the same meanings as before.

Therefore the series

$$\sum_{n} P\left(|D_{n\hat{k}}| - \frac{\hat{k}}{n}h_{n} \le |D_{nk}| - \frac{k}{n}h_{n},\right.$$

$$for some k with \left|\frac{k}{n} - t_{1}\right| > \frac{2m}{n}$$

$$and \left|\frac{k}{n} - t_{2}\right| > \frac{2m}{n}\right) < \infty.$$

Thus

$$\begin{split} P\bigg(\exists N: n \geq N \implies |D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n > |D_{nk}| - \frac{k}{n}h_n \\ & \quad for \ all \ k \ with \ |\frac{k}{n} - t_1| > \frac{2m}{n} \\ & \quad and \ |\frac{k}{n} - t_2| > \frac{2m}{n}\bigg) = 1. \end{split}$$

Suppose the event in the last  $P(\ )$  is true, and  $|\frac{I_1}{n}-t_1|\leq \frac{2m}{n}$  is true for large n. Then,  $|\hat{k}-I_1|=n|\frac{\hat{k}}{n}-\frac{I_1}{n}|\geq n(|t_2-t_1|-\frac{1}{2n}-\frac{2m}{n})>4m$ , if n is large. So,  $|D_{nI_2}|-\frac{I_2}{n}h_n\geq |D_{n\hat{k}}|-\frac{\hat{k}}{n}h_n$ , and  $|\frac{I_2}{n}-t_1|\leq \frac{2m}{n}$  or  $|\frac{I_2}{n}-t_2|\leq \frac{2m}{n}$ , for large n a. s. But  $|\frac{I_2}{n}-t_1|\geq |\frac{I_2-I_1}{n}|-|\frac{I_1}{n}-t_1|>\frac{4m}{n}-\frac{2m}{n}=\frac{2m}{n}$ , so  $|\frac{I_2}{n}-t_2|\leq \frac{2m}{n}$  for large n a. s.

From  $|D_{nI_2}| - \frac{I_2}{n}h_n \ge |D_{n\hat{k}}| - \frac{\hat{k}}{n}h_n$ , we have  $\liminf_{n\to\infty} |D_{nI_2}| \ge |d_2|$ . By the lemma, we must have  $D_{nI_2}\to d_2$ , a. s.

3. In this part we prove that  $D_{nI_{q+1}} = \mathcal{O}(h_n)$ , a. s. By definition,  $|I_{q+1} - I_i| > 4m, i = 1, \dots, q$  for sufficiently large n, a. s. Thus, in this case.

$$\left|\frac{I_{q+1}}{n}-t_i\right|>\frac{4m}{n}-\frac{2m}{n}=\frac{2m}{n}.$$

Therefore in  $\left[\frac{I_{q+1}-m}{n}, \frac{I_{q+1}+m}{n}\right]$  there are no discontinuity points, so

$$\begin{split} |D_{nI_{q+1}}| &\leq |\Delta_{I_{q+1}}| + |W_{I_{q+1}}^+| + |W_{I_{q+1}}^-| \\ &\leq K \frac{2m}{n} + |W_{I_{q+1}}^+| + |W_{I_{q+1}}^-|, \end{split}$$

and

$$\sum P\left(|D_{nI_{q+1}}| \ge h_n\right)$$

$$\le \sum P\left(h_n \le K\frac{2m}{n} + |W_{I_{q+1}}^+| + |W_{I_{q+1}}^-|\right)$$

$$\le b \sum_n nP\left(b_1h_n \le \left|\frac{v_1 + \dots + v_m}{m}\right|\right)$$

$$\le b \sum_n nP(b_2\sqrt{m}h_n \le |z|) < \infty.$$

Therefore

$$|D_{nI_{q+1}}| = O(h_n), \quad a. \ s.$$
